

Efficiency in multiple prediction, leveraging the CMP gather

Matthew Eaid and Kris Innanen

Talk Outline

1. Motivation
2. Review of multiple prediction based on the inverse scattering series
3. 2D versus 1.5D prediction algorithms
4. Traveltime equations, the CMP gather, and the impact on multiple prediction
5. Examples
6. Conclusions

Motivation

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

- 2D internal multiple prediction is a time consuming and computationally exhaustive process
- 1.5D algorithms are much more efficient, however, applying them to datasets acquired over 2D geology is typically a fruitless endeavor
- Our goal is to develop methods for successful application of 1.5D prediction algorithms to 2D datasets, improving efficiency, while maintaining a robust level of accuracy.

Review of Inverse Scattering Multiple Prediction

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

Review of Inverse Scattering Multiple Prediction

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

A diagram illustrating the decomposition of a multiple reflection into primary and secondary reflections. A purple zigzag line is shown on the left, followed by an equals sign, a plus sign, and a minus sign.

Review of Inverse Scattering Multiple Prediction

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

$$\text{Purple V-shape} = \text{Red V-shape} + \text{Blue V-shape} -$$

The equation shows a purple V-shaped waveform on the left, followed by an equals sign, then a red V-shaped waveform, a plus sign, a blue V-shaped waveform, and a minus sign. This represents the decomposition of a complex waveform into two simpler components.

Review of Inverse Scattering Multiple Prediction

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

- Fully data driven algorithm for prediction all first order internal multiples in dataset with correct phase, and approximate amplitude
- Combines events in the data that obey a lower-higher-lower relationship to automatically predict internal multiples

The diagram shows the equation: $\text{Purple Path} = \text{Red Path} + \text{Blue Path} - \text{Green Path}$. This illustrates how a complex multiple reflection path (purple) can be decomposed into the sum of primary reflections from the first and second interfaces (red and blue) minus the primary reflection from the third interface (green).

Internal Multiple Prediction in 2-Dimensions

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

$$p_g = \frac{\sin\theta_g}{v_0}$$

$$p_1 = \frac{\sin\theta_1}{v_0}$$

$$p_2 = \frac{\sin\theta_2}{v_0}$$

$$p_s = \frac{\sin\theta_s}{v_0}$$

$$b_{3_{IM}}(p_g, p_s, \omega) = \frac{1}{(2\pi)^2} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} dp_1 e^{-i\omega(\tau_{1g} - \tau_{1s})} dp_2 e^{-i\omega(\tau_{2g} - \tau_{2s})} \times \Omega(p_g, p_1, p_2, p_s | \epsilon)$$

$$\Omega(p_g, p_1, p_2, p_s | \epsilon) = \int_{-\infty}^{\infty} b_1(p_g, p_1, \tau) e^{i\omega\tau} d\tau \int_{-\infty}^{\tau - \epsilon} b_1(p_1, p_2, \tau') e^{-i\omega\tau'} d\tau' \int_{\tau' + \epsilon}^{\infty} b_1(p_2, p_s, \tau'') e^{i\omega\tau''} d\tau''$$

Reduction to 1.5D

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

When flat layers exist in the subsurface, and $p_g = p_s = p_1 = p_2$ the problem reduces to 1.5D, and the resulting prediction equation simplifies to:

$$b_{3IM}(p_g, \omega) = \int_{-\infty}^{\infty} b_1(p_g, \tau) e^{i\omega\tau} d\tau \int_{-\infty}^{\tau-\epsilon} b_1(p_g, \tau') e^{-i\omega\tau'} d\tau' \int_{\tau'+\epsilon}^{\infty} b_1(p_g, \tau) e^{i\omega\tau''} d\tau''$$

Slant Stack and 1.5D Data Preparation

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

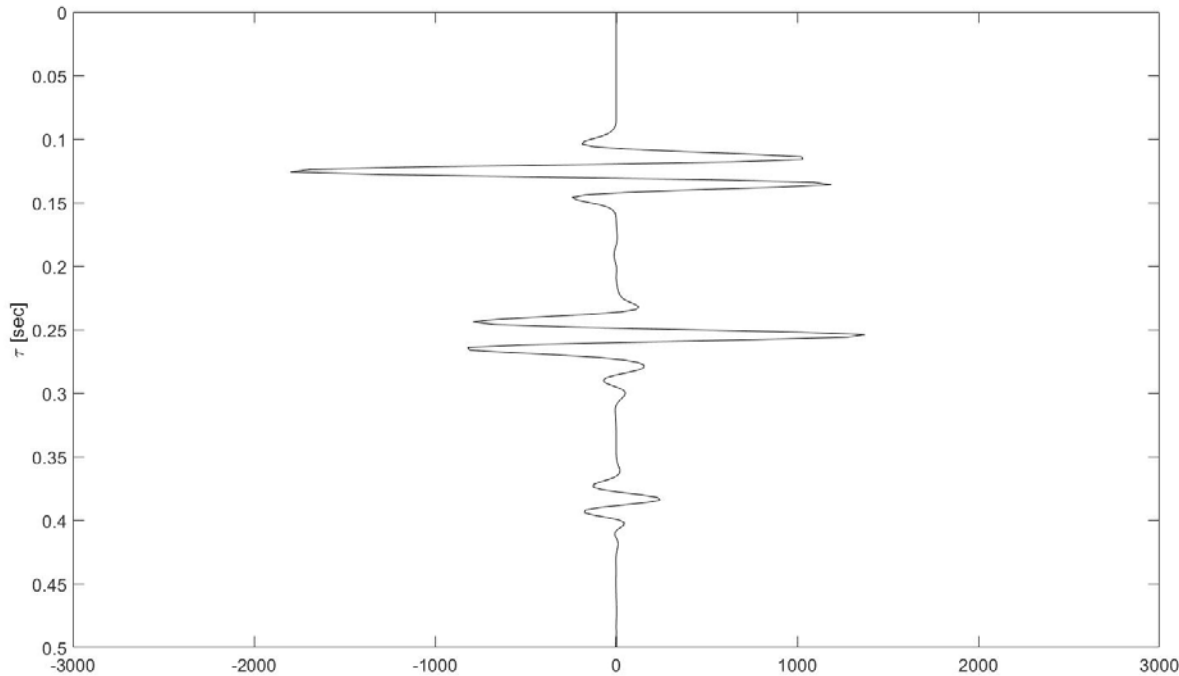

$$\Psi(p_g, \tau) = \int \Psi(x_g, \tau + p_g x) dx$$

- Inputs to the 1.5D algorithm are simply created by a standard slant stack over receiver side horizontal slowness
- Each trace is the response of a single plane wave component traveling with horizontal slowness p_g .
- The prediction algorithm then searches for events to combine in vertical travel time τ .

Slant Stack and 1.5D Data Preparation

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

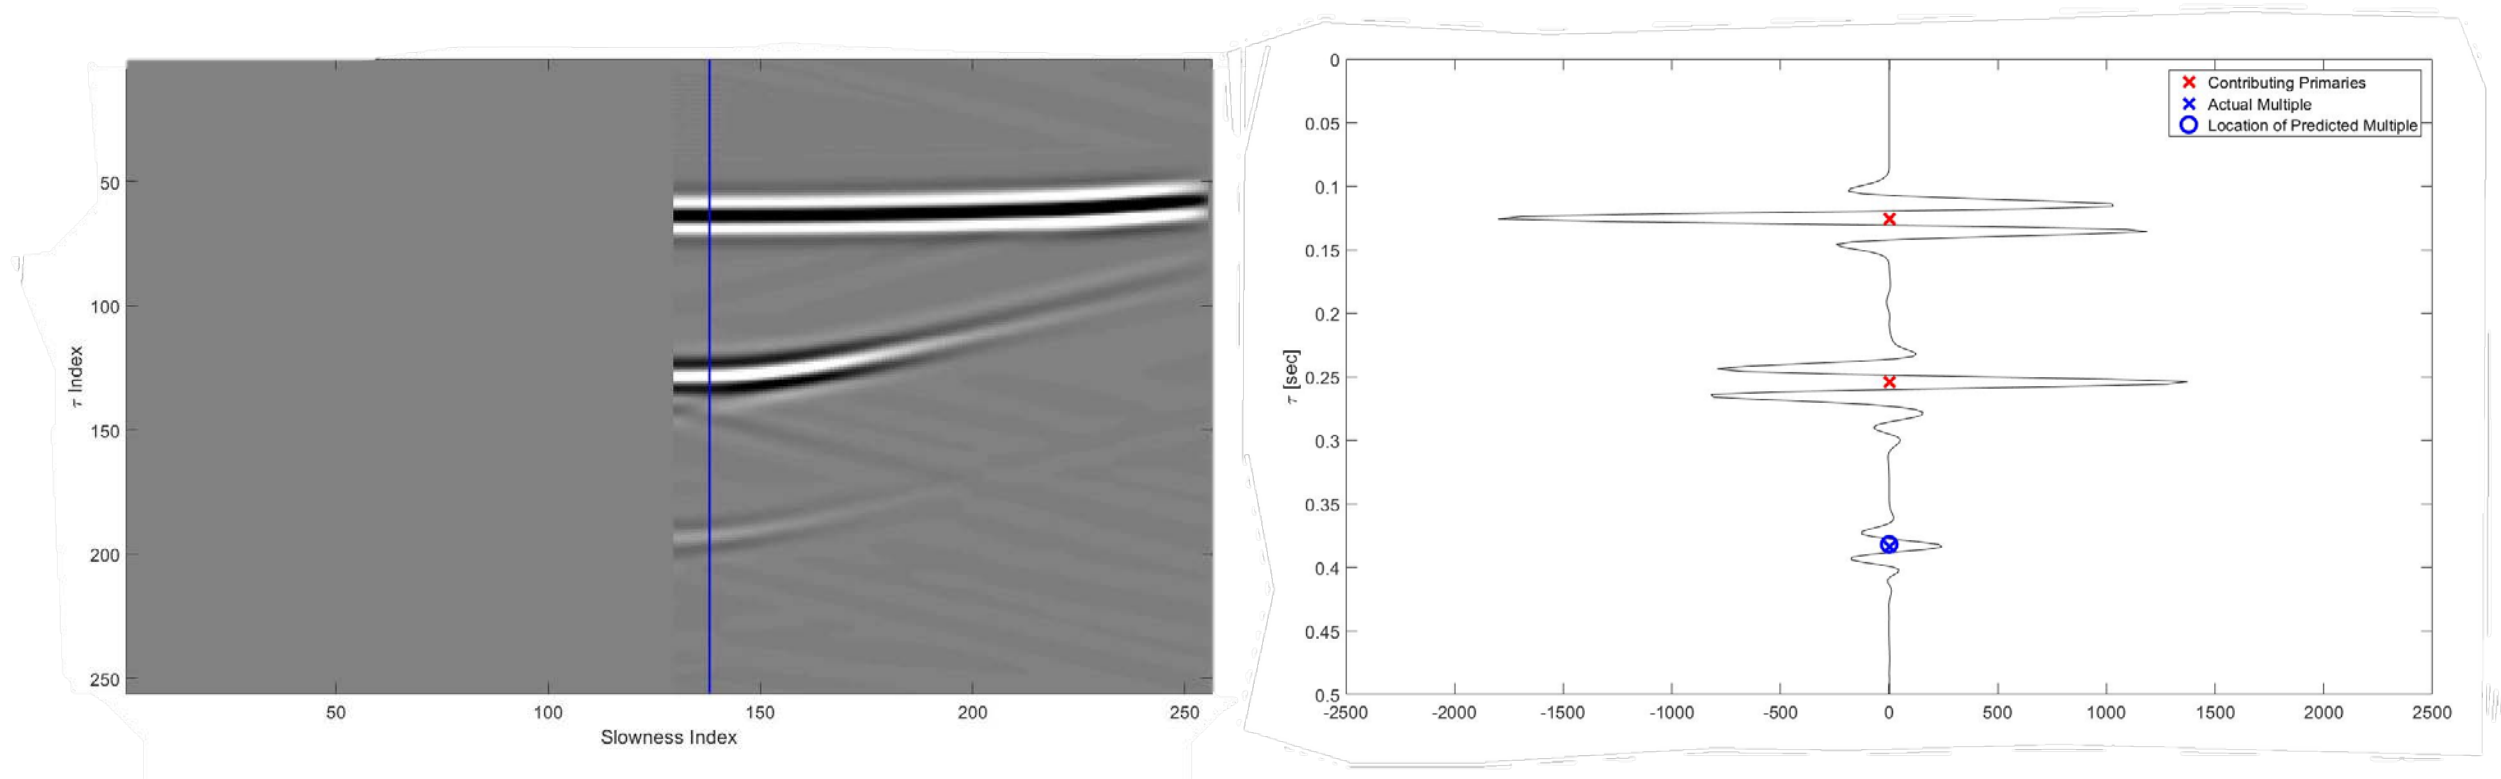

$$\Psi(p_g, \tau) = \int \Psi(x_g, \tau + p_g x) dx$$

- Inputs to the 1.5D algorithm are simply created by a standard slant stack over receiver side horizontal slowness
- Each trace is the response of a single plane wave component traveling with horizontal slowness p_g .
- The prediction algorithm then searches for events to combine in vertical travel time τ .

Issues Associated with Applying 1.5D Algorithms to 2D Data

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

Issues Associated with Applying 1.5D Algorithms to 2D Data

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

Traveltime Equation in Dipping Strata

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

For a fixed source (or receiver) at location A, the travel time of the ray shown is:

$$T = p_B x + \sum_j Z_{a_j} (q_{a_j} + q_{b_j})$$

Or for a fixed source (or receiver) at location B,

$$T = p_A x + \sum_j Z_{b_j} (q_{a_j} + q_{b_j})$$

Modified from Mota (1954) and Ocola (1972)

Traveltime Equation in Dipping Strata Relative to Reference

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

Modified from Mota (1954) and Ocola (1972)

When both A and B are moving, as in the CMP experiment neither equation is valid. If we let:

$$\frac{x_A + x_B}{X} = 1$$

$$z_j X = x_A z_B + z_A x_B$$

we may take a weighted average of the traveltime equations

$$T = \frac{x_B}{X} \left[p_B X + \sum_j z_{A_j} (q_{A_j} + q_{B_j}) \right] + \frac{x_A}{X} \left[p_A X + \sum_j z_{B_j} (q_{A_j} + q_{B_j}) \right]$$

Traveltime Equation for CMP Geometry

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

Modified from Mota (1954) and Ocola (1972)

$$T = \frac{x_B}{X} \left[p_B X + \sum_j z_{Aj} (q_{Aj} + q_{Bj}) \right] + \frac{x_A}{X} \left[p_A X + \sum_j z_{Bj} (q_{Aj} + q_{Bj}) \right]$$

$$T = x_A p_A + x_B p_B + \sum_j z_j (q_{Aj} + q_{Bj})$$

In the CMP experiment $x_A = x_B = \frac{X}{2}$

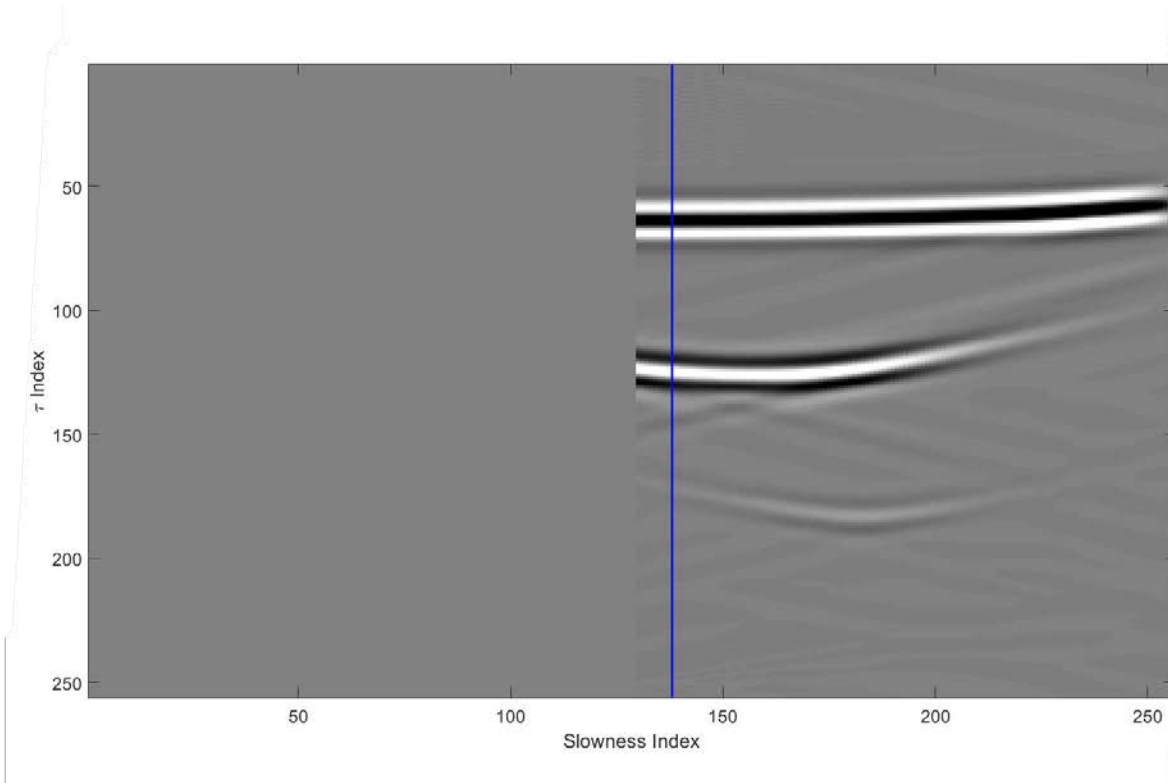

$$T = \frac{X}{2} (p_A + p_B) + \sum_j z_j (q_{Aj} + q_{Bj})$$

$$T = X \bar{p} + \sum_j z_j (q_{Aj} + q_{Bj})$$

Applying 1.5D Algorithms to 2D Data Revisited

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

Example for a Shot gather, over a model with an interface dipping at 16°

Comparisons of Shot Gather and CMP Gather Predictions

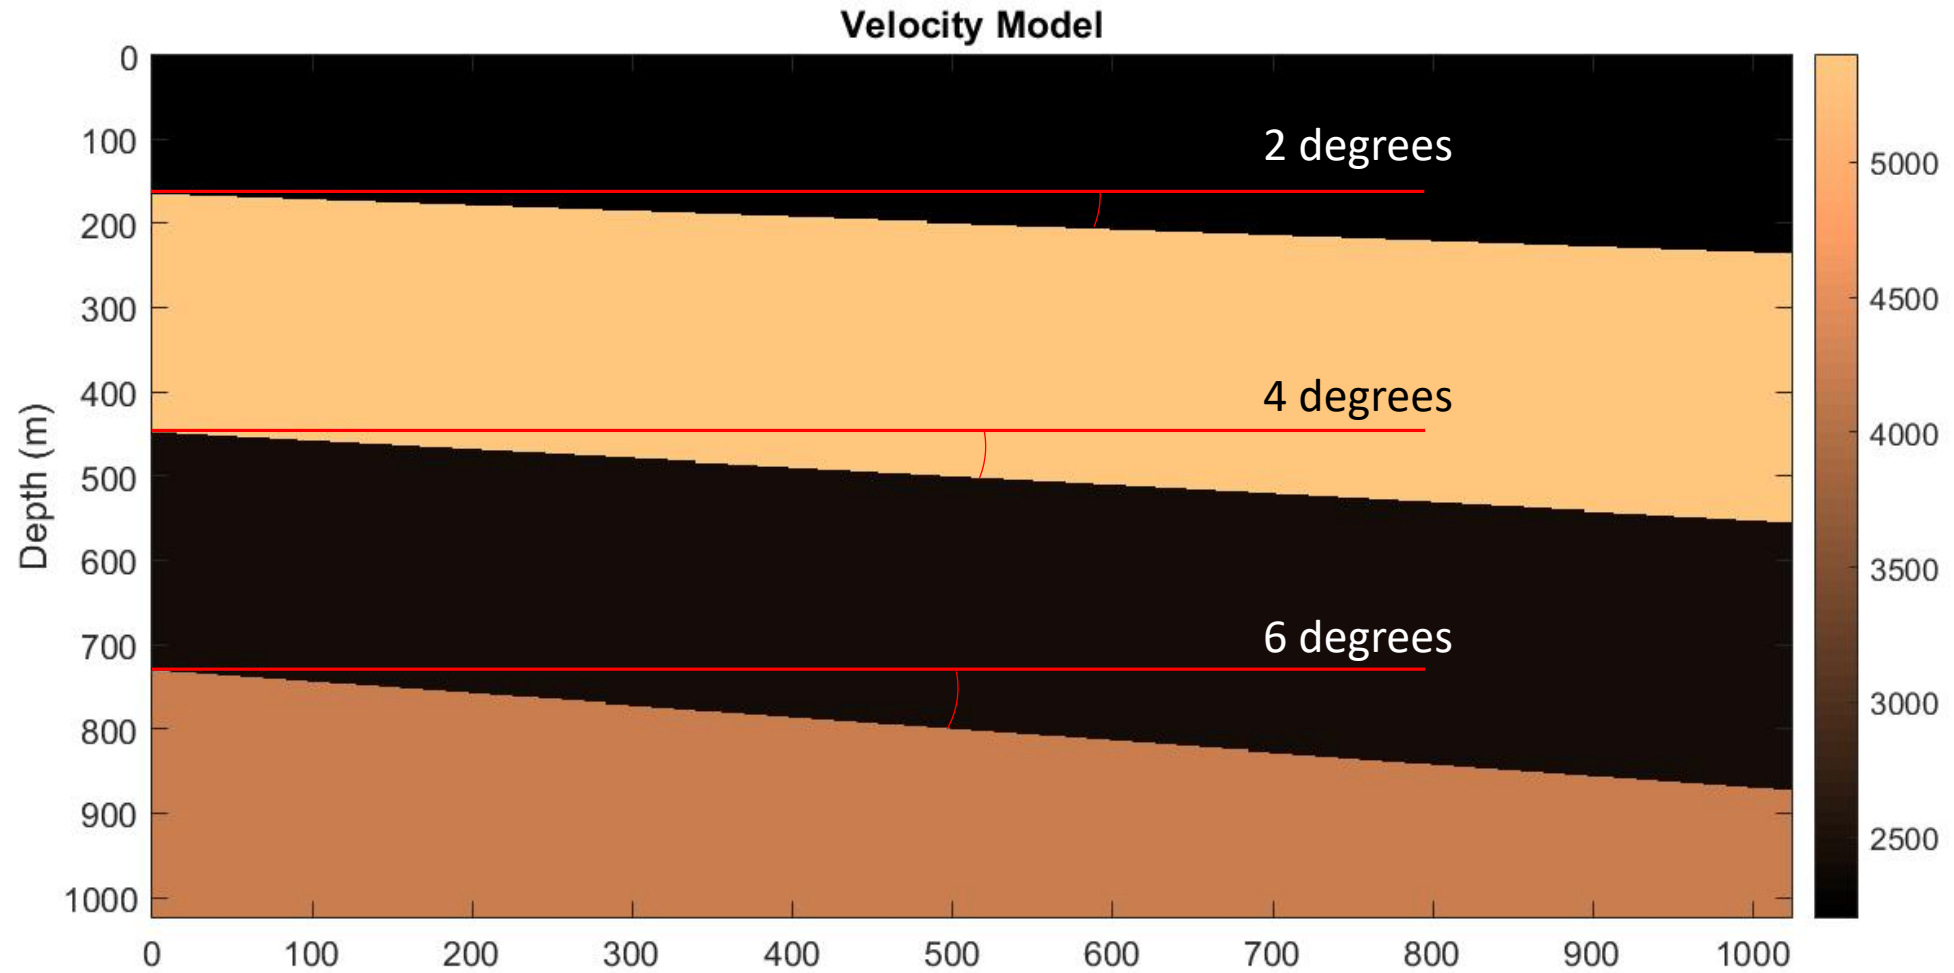

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

This graph shows the total energy removed by the prediction versus dip, relative to the energy removed in the “perfect” zero dip case for the CMP gathers (red) and the shot gathers (blue). Assuming all of the energy differences are related to the multiple being removed from the data and not dip induced changes in the reflection coefficients (which is approximately true), and keeping in mind that a value of 1 represents a perfect prediction, it can be seen that the CMP prediction performs much better than the prediction on the shot gather, as dip increases.

Conclusions

Motivation - Review – 2D & 1.5D Algorithms – Travel time and the CMP gather- Examples - Conclusions

- Methods of internal multiple prediction based on the inverse scattering series in both 2 and 1.5 dimensions were reviewed.
- Appropriate applications of each were discussed along with the tradeoff between cost and accuracy for different mediums.
- The 1.5D algorithm was shown to be unsuccessful in predicting multiples on shot gathers when the data was collected over 2D geology.
- However, when the prediction was performed on CMP gathers, which inherently averages the source side and receiver side slowness, it was shown that the 1.5D algorithm remains fairly robust in the presence of 2D geology.
- If dipping layers are expected, this workflow could improve prediction computation time.
