 - Real data
- ◆ Conclusions
- ◆ Acknowledgements

Introduction: Definition

- The Radon transform is defined as an integration of data along certain paths: such as hyperbola or parabola
- Basically, a point in the Radon domain stands for an event in the CMP domain
- Events with different velocities, such as primaries and multiples, map to different points in the Radon domain

Introduction: Definition

◆ Parabolic Radon transform in equations:

– Forward transform

$$u(q, \tau) = \sum_h d(t = \tau + qh^2, h)$$

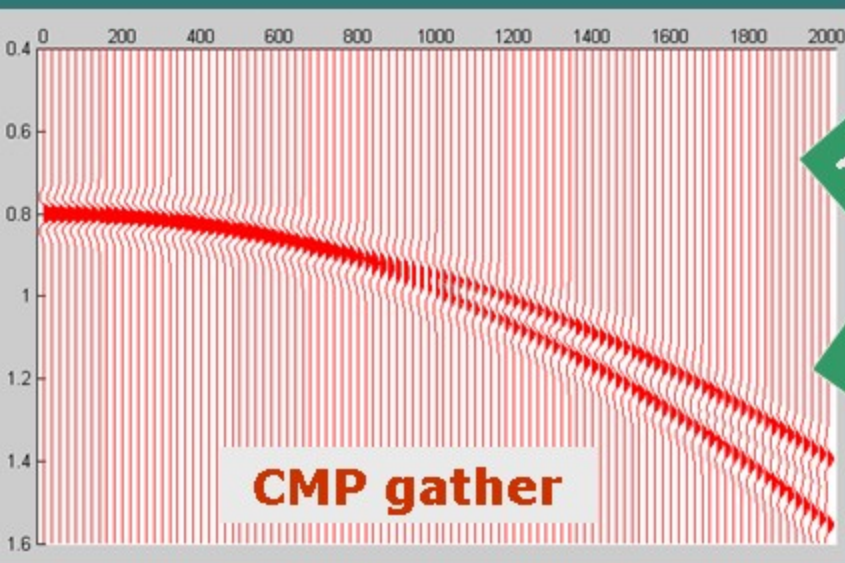

$$\mathbf{u} = \mathbf{L}^T \mathbf{d}$$

– Inverse transform

$$d(t, h) = \sum_q u(\tau = t - qh^2, q)$$

$$\mathbf{d} = \mathbf{L} \mathbf{u}$$

Problem 1: Smearing

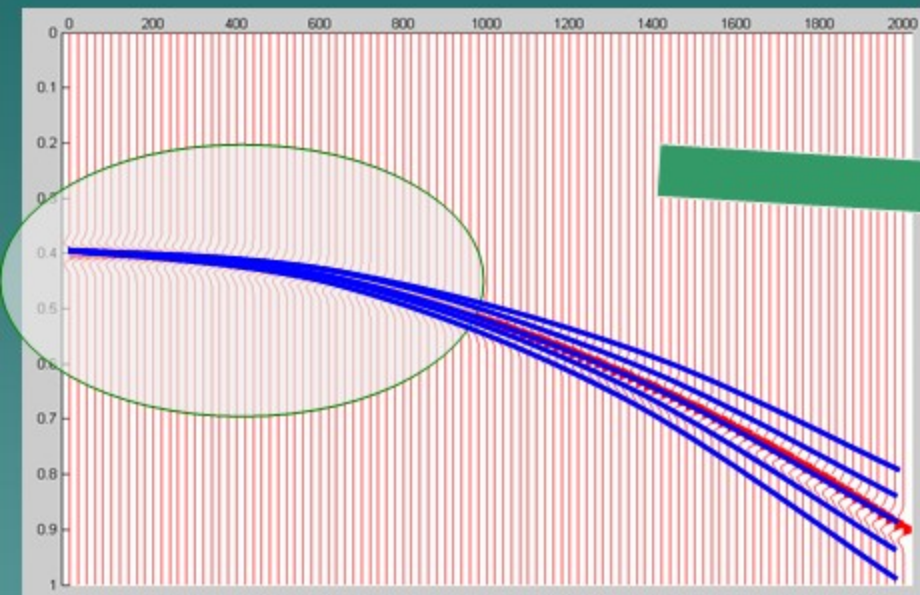

Ideal transform

Real transform

Why smearing

CMP gather

Radon panel

- Near offsets data are repeatedly transformed into the Radon domain;
- Near offsets energy sharing causes smearing problem.

Problem 2: data loss

- ◆ Radon transform is not an orthogonal algorithm, which means we lose data when we perform the Radon transform.

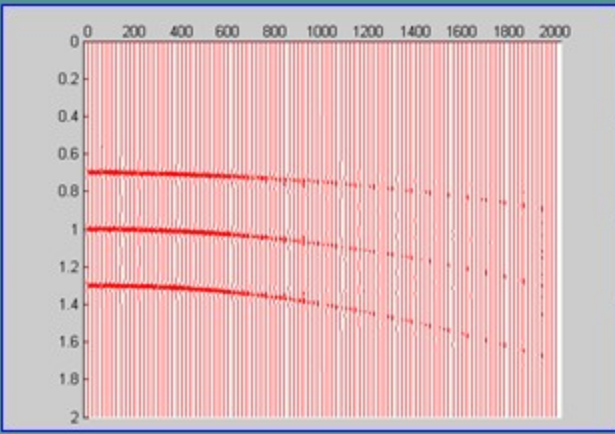

Forward

Inverse

Forward

Inverse

Semblance-weighted Radon transform

◆ Objectives:

- Reduce the smearing problem in the Radon domain and improve the resolution
- Prevent data loss

Semblance-weighted Radon transform

◆ Step 1 - weighting

- Weighting the transform with the semblance of the input gather;
- Semblance is defined in a similar way with the Radon Transform. The only difference is that semblance is independent of amplitudes of events and it ranges from 0-to-1;

◆ Step 2 - sorting

- Find out the most important traces in the Radon domain;
- First transform data along these important traces and remove the corresponding data from the input gather.

Semblance-weighted Radon transform

- ◆ Forward Radon transform:

$$u(q, \tau) = \sum_h d(t = \tau + qh^2, h)$$

- ◆ Semblance:

$$S(q, \tau) = \frac{\sum_l \sum_h (d(t = \tau + qh^2, h))^2}{N_h \sum_l \sum_h d^2(t = \tau + qh^2, h)}$$

- Same integration paths with the Radon transform;
- Values are normalized to 0-to-1, dependent of amplitudes;
- Offers coherency measurement of events;
- Weight the Radon transform with semblance will improve the Radon resolution.

Semblance-weighted Radon transform

Semblance-weighted Radon transform

Step 2: Sorting

CMP gather

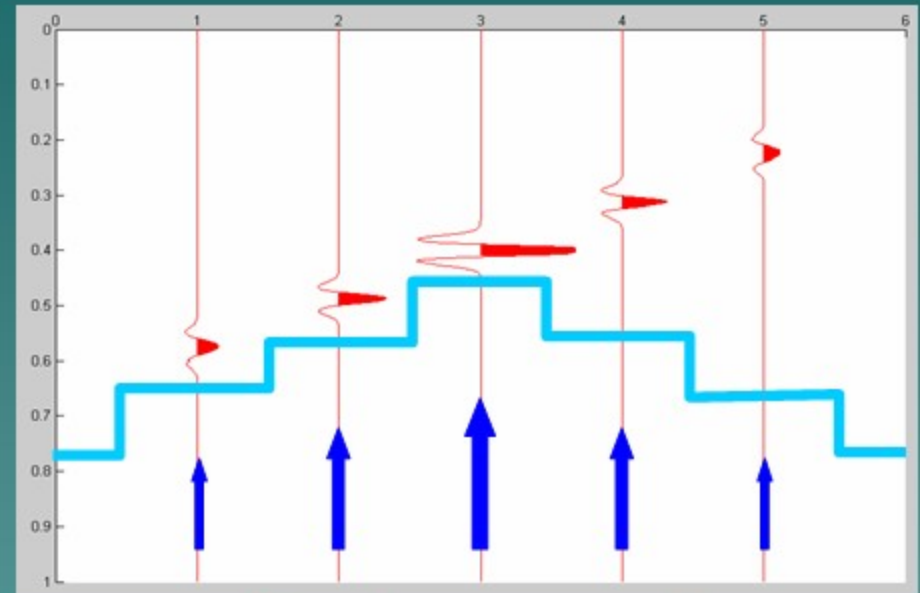

Radon panel

- Near offsets data are repeatedly transformed into the Radon domain, which causes smearing problem;
- How to avoid transforming data repeatedly?
- If it is avoided, can we reduce the smearing?

Semblance-weighted Radon transform

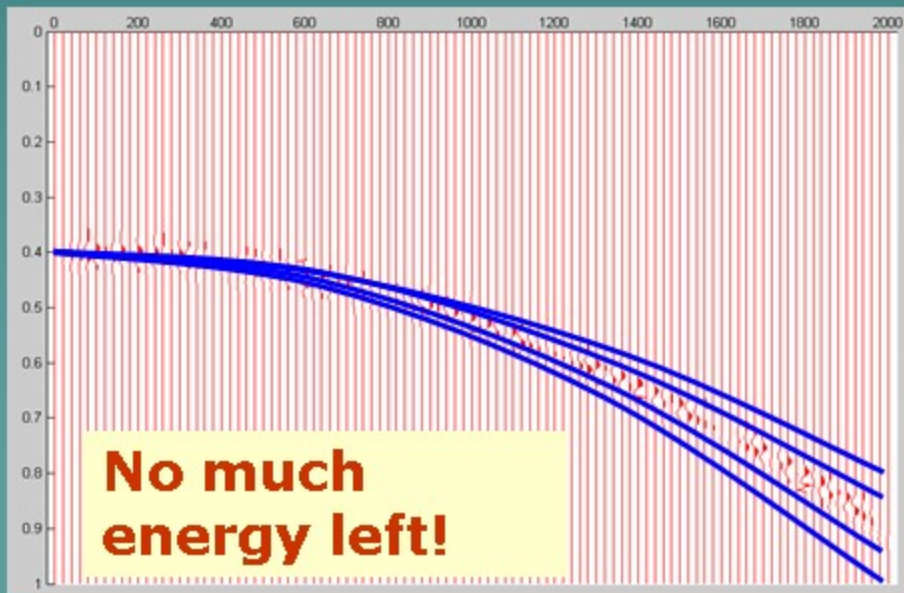

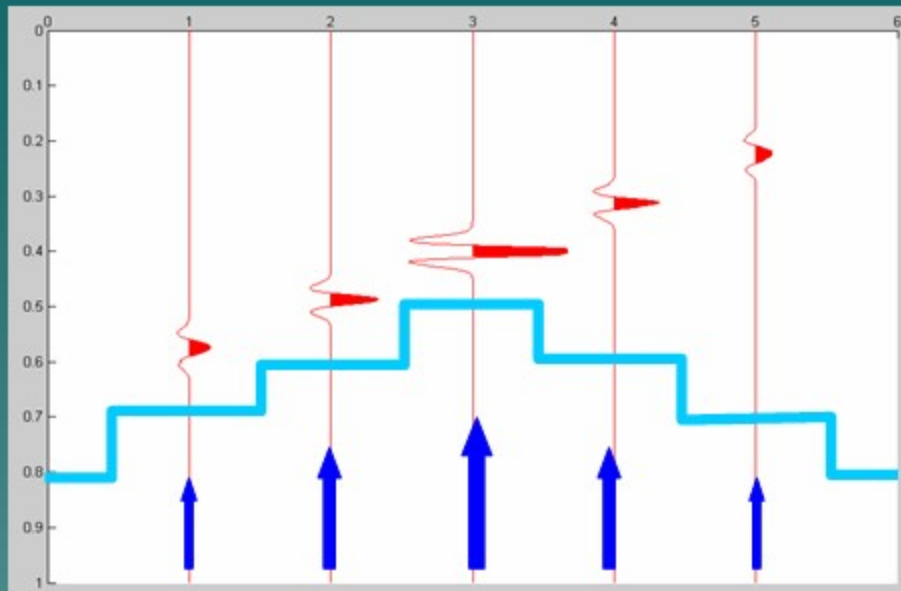

CMP gather

Radon panel

- Once a Radon panel is obtained by the semblance-weighted method, energy along each trace is estimated;
- A new turn of Radon calculation is first performed along the most powerful trace and corresponding data will be removed from the input.

Semblance-weighted Radon transform

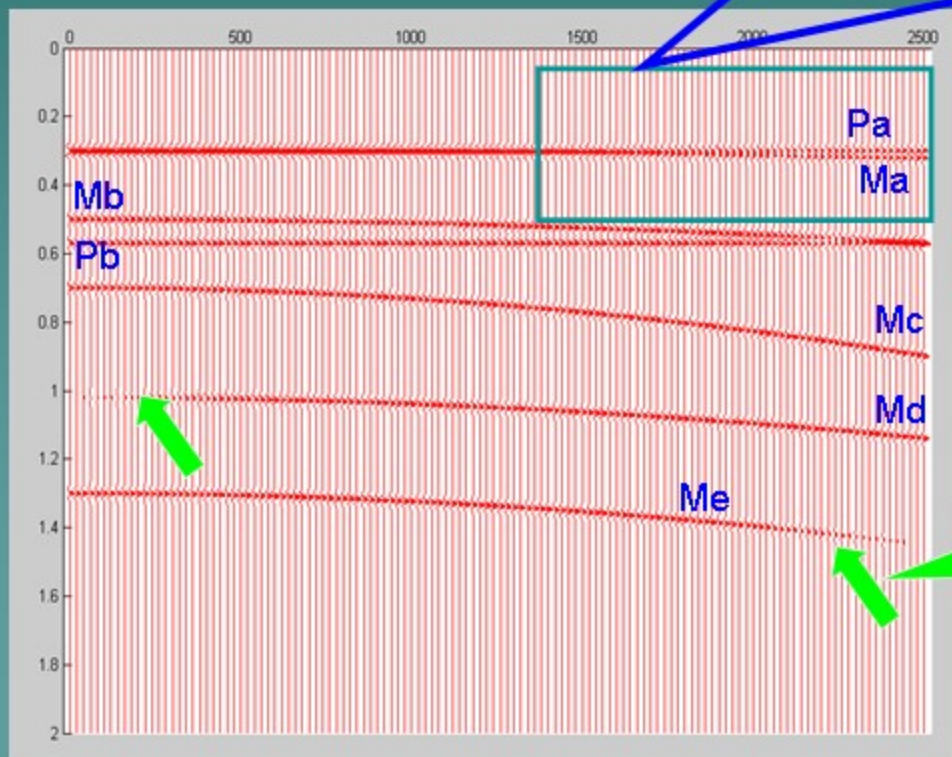

Example: synthetic data

NMO-corrected
CMP gather

Two events

20 ms between the peaks

AVO effect

Example: synthetic data

- ◆ Two things: resolution and data loss
- ◆ Reconstructed Gather = Gather obtained by inverse transforming the Radon Panel
- ◆ Residual Gather = Original Gather - Reconstructed Gather

The tool to examine if any data loss or how much data loss

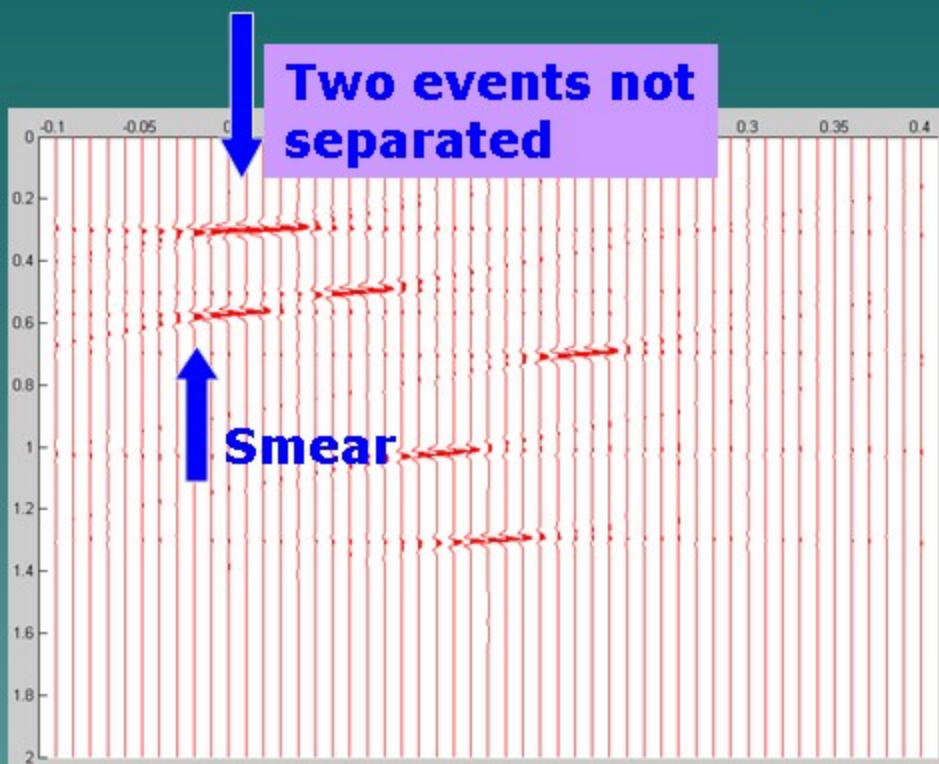

The less energy this gather contains, the less data loss happens.

Example: synthetic data

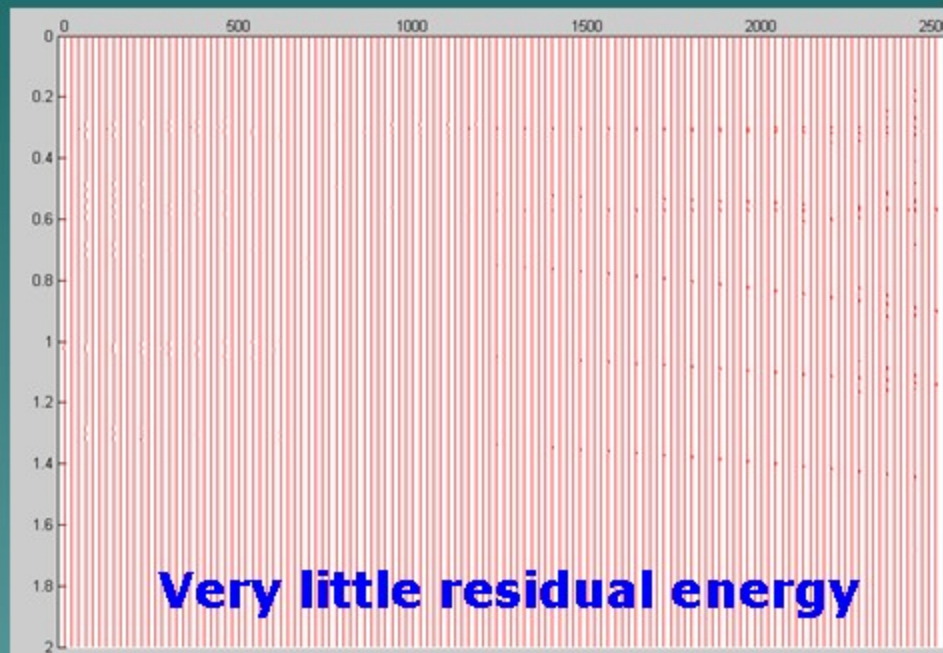

◆ Methods:

- Least-squares solution (Thorson and Claerbout, 1985; Hampson 1986; Beylkin, 1987; Yilmaz, 1989)
- Frequency domain high resolution method (Sacchi and Ulrych, 1995)
- Semblance-weighted Radon transform (Ng and Perz, 2004)

Radon Panel

Residual Gather

Synthetic Data: multiple attenuation

If primaries are muted, a multiple only CMP gather can be reconstructed from the residual energy.

Demultiplied Gather

Velocity Analysis

Multiple Reflections

Conclusions

- ◆ The three Radon methods examined can preserve data well;
- ◆ The semblance weighted high resolution Radon method gives the best resolution in the Radon panel;
- ◆ The Radon transform is a very powerful application on multiple attenuation as long as multiples have different velocities from primaries.
- ◆ After demultiplied, velocity analysis becomes easy work.
