

# Subtracting internal multiples in the generator domain

Scott Keating, Andrew Iverson and Kris Innanen

December 10<sup>th</sup> 2019

Events with at least one downward reflection and no surface reflections

Usually harmful in seismic processing and interpretation

# Multiple prediction

$$A_P = -R_2 R_1 R_2$$

$R_1$

$R_2$

$$A_D = -R_2 R_1 R_2$$

# Multiple prediction

# Multiple prediction

# Adaptive subtraction

# Multiple-prediction errors

$$A_P = A_0 \alpha_1^6 \alpha_2^4$$

$$A_D = A_0 \alpha_1^2 \alpha_2^4$$

# Multiple-prediction errors

$$A_P = A_0 \alpha_1^6 \alpha_2^6 \alpha_3^6 \alpha_4^4$$

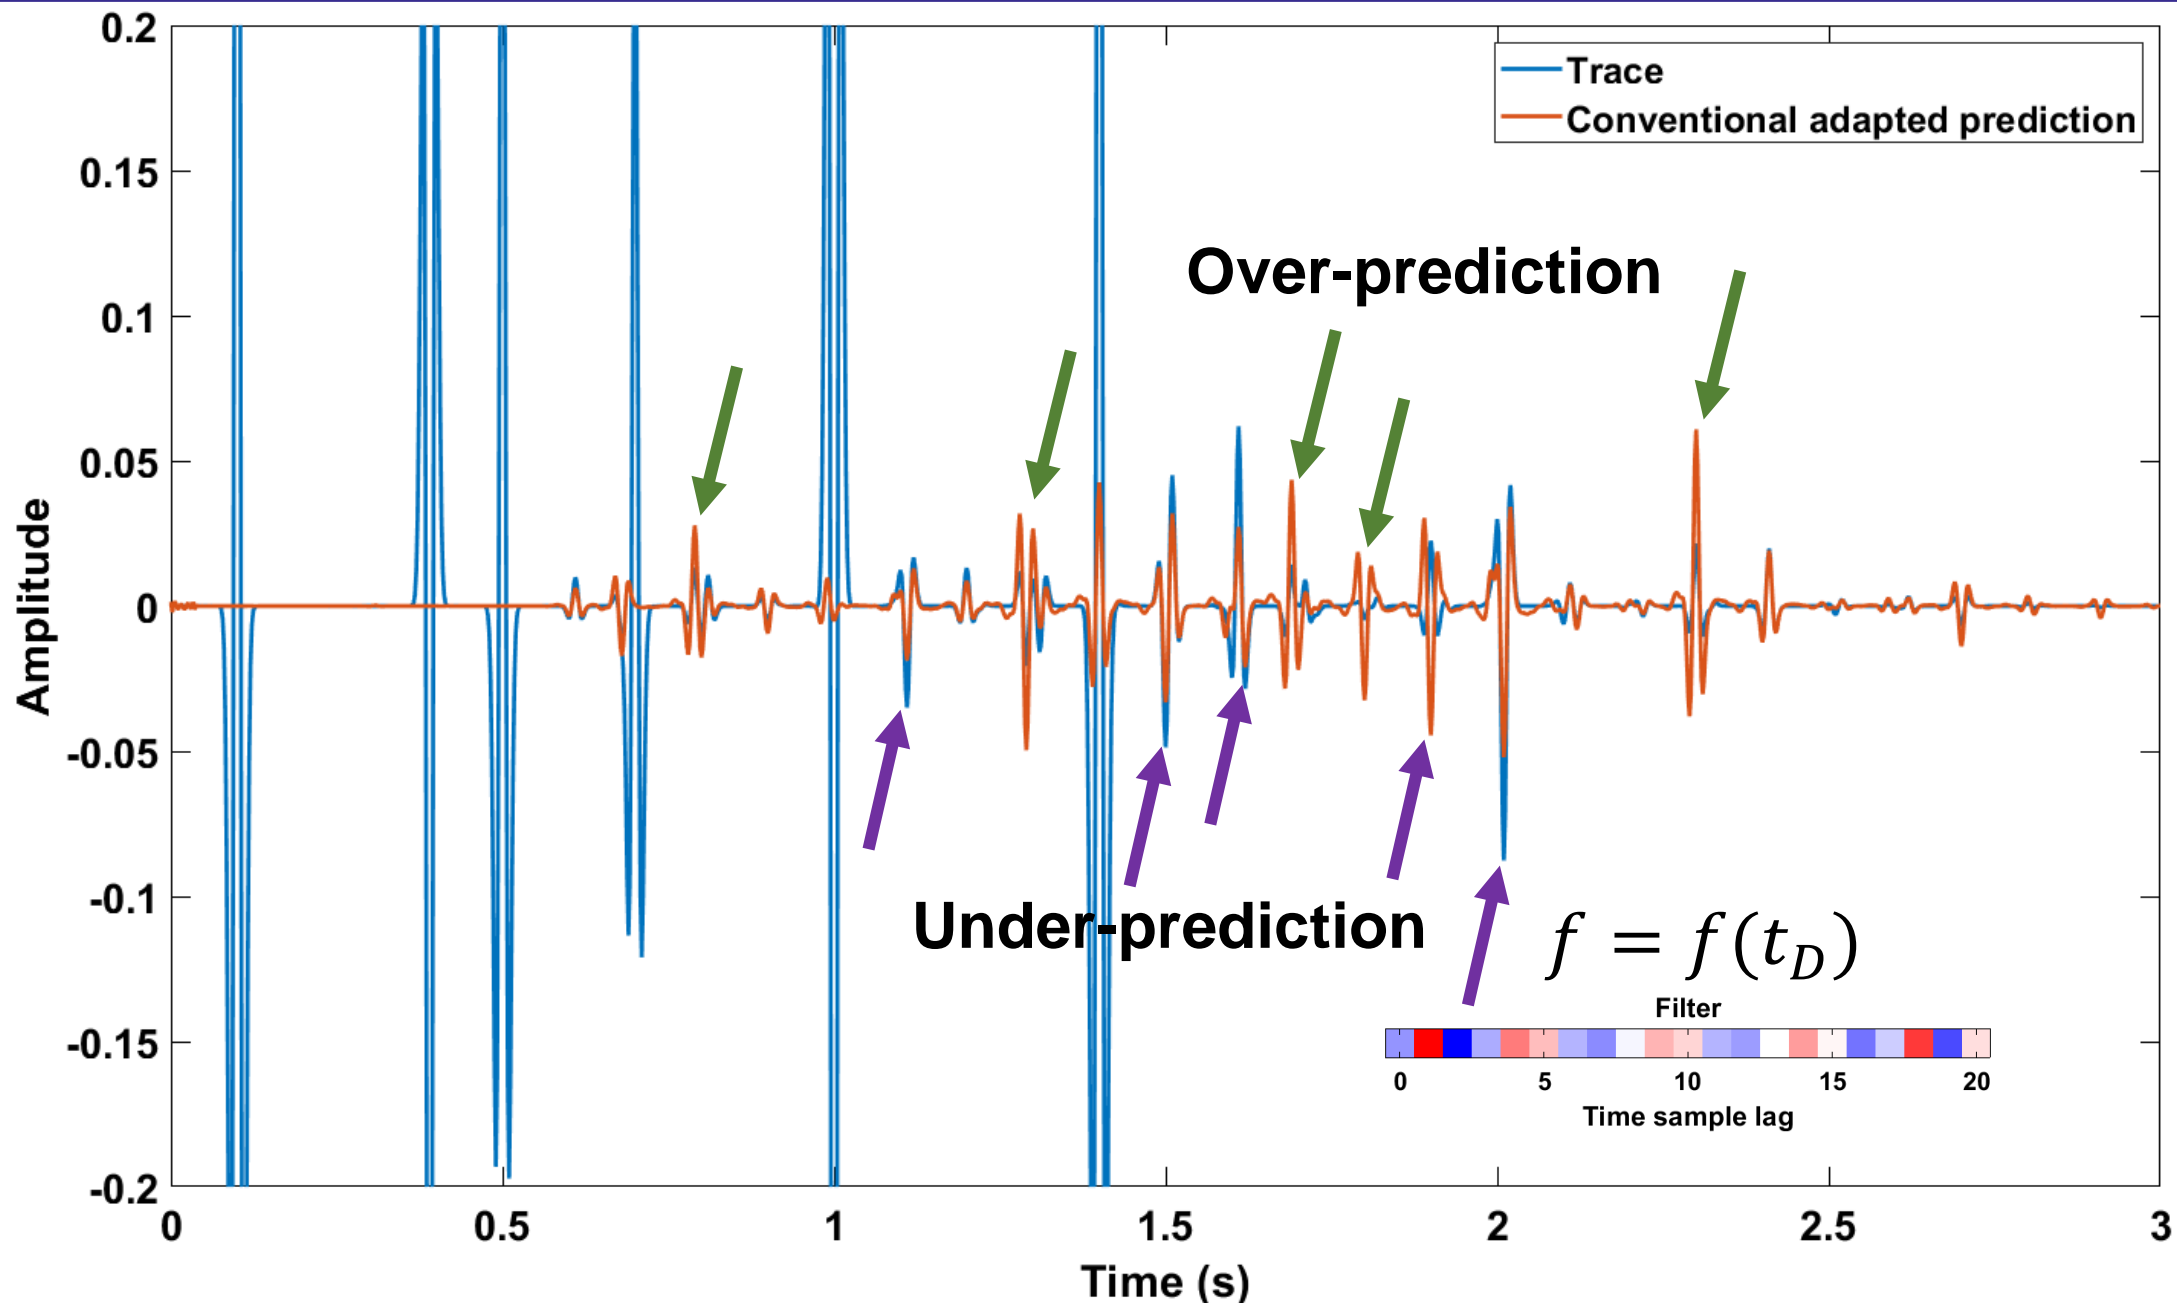

$$A_D = A_0 \alpha_1^2 \alpha_2^2 \alpha_3^6 \alpha_4^4$$

# Multiple-prediction errors

How can we make  
these errors consistent  
or predictable?

$$f = f(t_D)$$

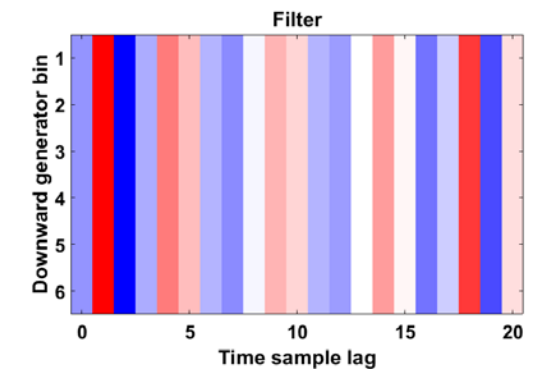

# The downward generator domain

$$f = f(t_D)$$

# Amplitude-corrected DG domain prediction

# Conventional prediction

- Transmission related losses aren't correctly treated in conventional ISSIMP
- This makes effective multiple removal very difficult
- Applying adaptive subtraction in the DG domain allows for better treatment of these losses

- CREWES sponsors, staff and students
- SEG and CSEGF
